Case A: high-rise building

Wind velocities were measured at 66 points distributed across 10 vertical lines intersecting the building symmetrically and parallel to the flow, and at 60 points along two sets of 9 horizontal lines perpendicular to the flow, at two heights $z=0.125b$ and $z=1.25b$. The length b is equal to 0.08m.

Velocity and turbulence profiles as a function of height are provided. In Vento AEC, a Power law inlet wind profile will be assigned, while the inlet turbulence profile assigned as a constant value, set to $0.55 \text{ m}^2/\text{s}^2$, corresponding to 12% turbulence intensity.

The simulation was performed using the k-epsilon (RANS) turbulence model, following the guidance of the reference paper.

Case A: high-rise building

VENTO AEC CFD simulation

VENTO AEC: 570 K cells, K & Epsilon turbulence model.

The convergence level -5 was reached in less than 30 min on a 2-cores desktop with CFL=100. Forces were stable after 15 min.

Case A: high-rise building

VENTO AEC results vs reference

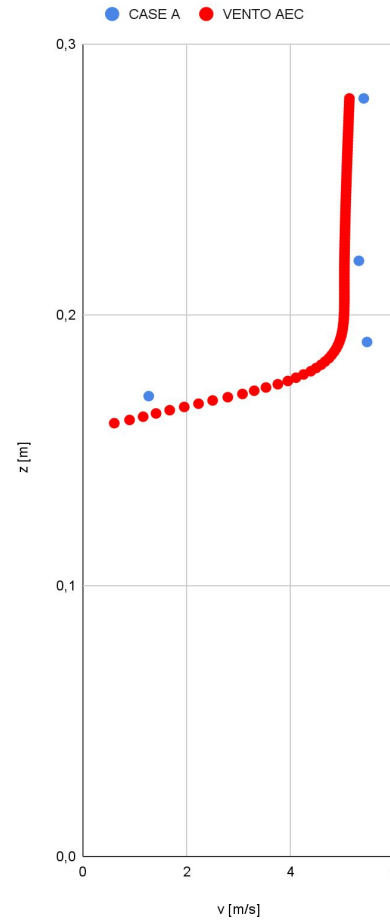

Vertical sections @ $y=0$

Velocity magnitude distribution on the vertical sections: VENTO AEC (red dots), and wind tunnel (blue dots)

Ver. Sect. $x=-0.06m$

Ver. Sect. $x= 0.00m$

Ver. Sect. $x= 0.06m$

Ver. Sect. $x= 0.10m$

Case A: high-rise building

VENTO AEC results vs reference

Horizontal sections $z=0.01\text{m}$

Velocity magnitude distribution on the horizontal sections at $z=0.01\text{m}$: VENTO AEC (red dots), and wind tunnel (blue dots)

Ver. Sect. $x=-0.06\text{m}$

Ver. Sect. $x=-0.02\text{m}$

Ver. Sect. $x=0.06\text{m}$

Ver. Sect. $x=0.10\text{m}$

Case A: high-rise building

VENTO AEC results vs reference

Horizontal sections $z=0.09\text{m}$

Velocity magnitude distribution on the horizontal sections at $z=0.09\text{m}$: VENTO AEC (red dots), and wind tunnel (blue dots)

Ver. Sect. $x=-0.06\text{m}$

Ver. Sect. $x=-0.02\text{m}$

Ver. Sect. $x=0.06\text{m}$

Ver. Sect. $x=0.10\text{m}$
